

## Exercises

ANNA SOMOZA

**Exercise 1.** Let  $M \in \mathbb{Z}^{n \times n}$  be a unimodular matrix.

(i) Show that  $M$  is invertible, and that  $M^{-1}$  is unimodular.

(ii) Show that if  $n = 2$ , then  $M$  is equal to  $\pm I_n$  or  $\pm \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$  times a combination of the matrices  $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ ,  $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$  and their inverses.

(iii) Prove that two bases with matrices  $B$  and  $C$  generate the same lattice if and only if there exists a unimodular matrix  $M \in \mathbb{Z}^{n \times n}$  such that  $B = CM$ .

**Exercise 2.** Let  $\Lambda \subseteq \Lambda'$  be two full rank lattices. Prove that if  $\det \Lambda = \det \Lambda'$ , then  $\Lambda = \Lambda'$ . Prove also that if  $\Lambda \neq \Lambda'$ , then  $\det \Lambda \geq 2 \det \Lambda'$ .

**Exercise 3.** Let  $\Lambda$  be a lattice of dimension  $n$ . Show that the number of vectors  $x \in \Lambda$  such that  $\|x\| = \lambda(\Lambda)$  is upper-bounded by  $3^n$ . This number is called the kissing number. One can look at the volume of the open balls centered on these points and with radius  $\lambda(\Lambda)/2$ .

**Exercise 4.** The goal of this exercise is to prove that every lattice  $\Lambda$  of dimension  $n$  has at most  $2^{O(n^3)}$  reduced bases.

(i) Let  $\lambda = \lambda(\Lambda)$  be the minimal distance of  $\Lambda$ , and let  $(b_1, \dots, b_n)$  be a reduced basis. Show that  $\|b_1\| \leq r$  with  $r = 2^{O(n)}\lambda$ .

(ii) Consider a ball of radius  $r$  and the balls of radius  $\lambda/2$ . Show that there are at most  $2^{O(n^2)}$  points of the lattice of length smaller or equal to  $r$ . Conclude on the number of possibilities for  $b_1$ .

(iii) Consider now the projection  $(b'_2, \dots, b'_n)$  of the vectors  $(b_2, \dots, b_n)$  on the hyperplane orthogonal to  $b_1$ . Show that  $(b'_2, \dots, b'_n)$  is still a reduced basis (for the lattice generated by  $(b'_2, \dots, b'_n)$ ).

(iv) Show that  $b'_2$  cannot come from more than  $2$   $b_2$  of a reduced basis of  $\Lambda$  with  $b_1$  fixed.

(v) Deduce that the number of possible  $b_2$  is at most  $2^{O(n-1)^2}$ .

(vi) Conclude by recurrence the claim of the exercise.

**Exercise 5.** Let  $\Lambda$  be a lattice of dimension  $n$ .

(i) Using Minkowski's theorem<sup>1</sup> with a parallelepiped, show that there exists  $x \in \Lambda$  nonzero such that  $\|x\|_\infty \leq (\det L)^{1/n}$ .

---

<sup>1</sup>You may consider the following variant of Minkowski's Theorem:

**Corollary** (A variant of Minkowski's theorem). Let  $C$  be a compact centrally-symmetric convex set in  $\mathbb{R}^n$  such that  $\text{vol } C \geq 2^n \det \Lambda$ . Then there exists a nonzero element of  $\Lambda$  in  $C$ .

(ii) Show that for this  $x$ , we have  $\|x\|_2 \leq \sqrt{n}(\det L)^{1/n}$ .

We will now obtain a weaker, but constructive, result. Let  $b_i^* = b_i - \sum_{j < i} \mu_{ij} b_j^*$ .

(iii) Show by induction that we can always take  $\mu_{i,i-1} \leq 1/2$ , replacing  $b_i$  by  $b'_i = b_i - \lfloor \mu_{i,i-1} \rfloor b_{i-1}$  if necessary.

(iv) Show that the condition  $\|b_{i-1}^*\|_2 \leq \|b_i^* + \mu_{i,i-1} b_{i-1}^*\|_2$  can be interpreted geometrically in terms of the projection of  $b_{i-1}$  and  $b_i$  on  $\langle b_1, \dots, b_{i-2} \rangle^\perp$ .

(v) Deduce that the property above is true, swapping  $b_{i-1}$  and  $b_i$  if necessary.

We would like to obtain both properties at the same time. Consider the following algorithm:

---

**Algorithm 1:** Reduction procedure

---

Make all  $\mu_{i,i-1}$  smaller or equal to  $1/2$  in absolute value.

**while**  $\exists i_0, \|b_{i_0-1}^*\|_2 > \|b_{i_0}^* + \mu_{i_0,i_0-1} b_{i_0-1}^*\|_2$  **do**  
  Swap  $b_{i_0}$  and  $b_{i_0-1}$ .  
  Make all  $\mu_{i,i-1}$  smaller or equal to  $1/2$  in absolute value.

---

(vi) Show that the algorithm finishes because the norm tuple  $(\|b_1^*\|_2, \dots, \|b_n^*\|_2)$  decreases strictly on each iteration with respect to the lexicographic order.

(vii) Show that for  $i > 1$  we have  $\frac{3}{4} \|b_{i-1}^*\|_2^2 \leq \|b_i^*\|_2^2$  by the end of the algorithm.

(viii) Using the fact that  $\det \Lambda = \prod \|b_i^*\|_2$ , show Hermite's inequality

$$\|b_1\|_2 \leq \left(\frac{4}{3}\right)^{(n-1)/4} (\det \Lambda)^{1/n}.$$

**Exercise 6.** Consider the lattice  $\Lambda$  generated by the columns of the following matrix:

$$B = \begin{pmatrix} 2 & 0 & 0 & 1 \\ 0 & 2 & 0 & 1 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

We consider  $b'_4 = 2b_4 - b_1 - b_2 - b_3$ . Show that  $b_1, b_2, b_3, b'_4$  are linearly independent, and that they attain the minimal length 2, but that they do not generate the lattice  $\Lambda$ .

**Note:** In dimension  $\geq 5$ , there exist lattices for which no choice of vectors attaining the minimal length forms a basis of the lattice.

**Exercise 7.** In dimension 2, consider the following algorithm, where we use  $q(u) = \|u\|^2$ .

---

**Algorithm 2:** Gauss' algorithm

---

**input** : An ordered basis  $(u, v)$  with  $q(u) \leq q(v)$

**output:** A reduced basis of the lattice

**repeat**

$x = \lfloor \langle u, v \rangle / q(u) \rfloor$   
   $r = v - xu$   
   $v = u$   
   $u = r$

**until**  $q(u) \geq q(v)$ ;

**return**  $(v, u)$

---

First we focus on the correctness of the algorithm.

- (i) Show that the output  $(U, V)$  is a basis of the lattice
- (ii) Show that  $q(U) \leq q(V)$  and that for all  $y \in \mathbb{Z}$  we have  $q(V + yU) \geq q(V)$ .
- (iii) Using  $q(U + V) \geq q(V)$  and  $q(U - V) \geq q(V)$ , deduce that  $|\langle U, V \rangle| \leq q(U)/2$ .
- (iv) Show that  $q(U)$  is minimal by proving that if we have  $q(x_1U + x_2V) < q(U)$  then  $x_1 = x_2 = 0$ .
- (v) Show that  $q(V)$  attains the second minimum, that is, it is not possible to have  $q(x_1U + x_2V) < q(V)$  with  $x_2 \neq 0$ .

Now we focus on the execution time of the algorithm.

- (vi) Show that if  $x = 0$ , then it ends loop.
- (vii) Prove that  $|x| = 1$  can only occur on the two first or the last iteration of the algorithm. Do so by contradiction, by showing that then  $r$  is not the minimal choice.
- (viii) Assume  $|x| > 1$ . Prove that in that case we have  $\langle u, v \rangle / q(u) \geq 3/2$ .
- (ix) Let  $v^\perp$  be the projection of  $v$  on  $\langle y \rangle^\perp$ . Prove that  $q(v) \geq q(v^\perp) + 9/4q(u)$ .
- (x) Prove that  $q(r) \leq q(v^\perp) + 1/4q(u)$ .
- (xi) Deduce that  $q(v) \geq q(r) + 2q(u)$ , and that if we are not on the last iteration, then  $q(v) \geq 3q(r)$ .
- (xii) Deduce that, except on the first two or the last iteration of the algorithm,  $q(u)q(v)$  decreases by a factor of 3 on each iteration. Denote by  $\lambda_1$  the minimum of the lattice, and  $u_0, v_0$  the input vectors, and prove that the number of iterations is at most  $2 \log_3 q(v_0) / \lambda_1^2 + 2 = O(\log q(v_0))$ .
- (xiii) The cost of each step inside the loop is upper-bounded by the cost of the computation of  $x$ , that is an euclidean division. If we write  $a = bq + r$ , then the cost is  $O(\log(a)^2)$ . Deduce the total cost of the algorithm.
